1 Propositional Logic

Philosophers still debate about what a proposition really means. As a complete beginner, I mention some interpretations of it, but I by no means claim that this is the definitive definition.

Definition 1.1 (Possible World)

A **possible world** is a complete and consistent way the world is or could have been.

The **language** of propositional logic consists of just two things: propositions and connectives.

Definition 1.2 (Proposition)

A **proposition** does not have a formal definition, but we can describe it in the following ways.

1. They can be understood as an indicator function $f : W \rightarrow \{T, F\}^a$ that takes in a possible world and returns a truth value. We can also model it with the preimage of f under T , i.e. the characteristic set of f .
2. They deal with **statements**, which are defined as declarative sentences having a truth value. Propositions are either true or false.

Example 1.1 ()

The proposition that *the sky is blue* is represented as the function that returns T for every possible world where the sky is blue.

These declarative sentences are contrasted with questions, such as *how are you doing?* and imperative statements such as *please run my models*. Such non-declarative sentences have no truth value.

A statement can contain one or more other statements as parts. For example, compound sentences form simpler sentences.

Definition 1.3 (Connectives)

Statements are combined with **logical connectives**.

Connective	Symbols
AND	$A \wedge B, A \cdot B, AB, A \& B, A \& \& B$
OR	$A \vee B, A + B, A \mid B, A \parallel B$
NOT	$\neg A, -A, \overline{A}, \sim A$
NAND	$\overline{A \wedge B}, A \mid B, \overline{A \cdot B}$
NOR	$\overline{A \vee B}, A \downarrow B, \overline{A + B}$
XOR	$A \veebar B, A \oplus B$
XNOR	$A \odot B$
IMPLIES	$A \Rightarrow B, A \supset B, A \rightarrow B$
EQUIVALENT	$A \equiv B, A \Leftrightarrow B, A \leftrightarrow B$
NONEQUIVALENT	$A \nabla B, A \nrightarrow B, A \nleftrightarrow B$

Table 1: Logical Connectives and Their Symbols

^a T, F stands for True, False.

Definition 1.4 (Propositional Formula)

Propositions, represented by letters and denoted **propositional variables**, along with these symbols for connectives, combine to make a **propositional formula**.

Propositional logic is not concerned with the structures of propositions beyond the point where they cannot be decomposed any more by logical connectives.

1.1 Arguments

At this point we may look at a set of propositions P_1, \dots, P_n and try come to a logical conclusion Q . This is called an argument.

Definition 1.5 (Argument)

Let P be a set of propositions, called the **premises**. Let Q be a proposition, called the **conclusion**. Then an **argument** is an attempt to deduce Q from P . It is written in the forms

1. If P , then Q .
2. $P \implies Q$

An argument is **valid** if and only if

1. It is necessary that if P is true, Q is true.
2. It is impossible for P to be true, while Q is false.

Example 1.2 ()

The following is an argument.

1. If *it is raining*, then *it is cloudy*.
2. *It is raining*.
3. *Therefore it is cloudy*.

Logic in general aims to specify valid arguments. This is done by defining a valid argument as one in which its conclusion is a logical consequence of its premises. Determining whether a proposition is a logical consequence of another proposition is the process of **deductive argument**, which has rules. These rules, called **rules of inference**, determines the “legal moves” from one or more premises to the conclusion. We give 2 familiar ones.

Definition 1.6 (Modus Ponens)

Modus ponens is a deductive argument form and rule of inference.^a The argument states that given the premises

1. $P \implies Q$
2. P

Then our conclusion is Q .

The next one is the familiar statement that a statement is equivalent to its contrapositive.

Definition 1.7 (Modus Tollens)

Modus tollens is a deductive argument form and a rule of inference. The argument states that given the premises

1. $P \implies Q$
2. $\neg Q$

^aIn some literature it is treated as an axiom, though most people think of it as a rule.

Then our conclusion is not P .

2 First-Order Logic

In propositional logic, we deal with simple declarative propositions. **First-order logic** extends this by covering predicates and quantification. Let's motivate them.

We can think of predicates as properties. If we say *Socrates is a philosopher* and *Plato is a philosopher*, in propositional logic both these statements, represented as P and Q , as utterances that are either true or false, and they are completely independent from one another. However, we may want to view them as an application of a predicate ** is a philosopher* on the entities *Socrates* and *Plato*. This motivates the formalism of the domain of discourse and the predicate.

Definition 2.1 (Domain of Discourse)

Given an individual x , its **domain of discourse** is the set over which certain variables of interest in some formal treatment may range.

Definition 2.2 (Predicate)

A **predicate** P is a symbol that represents a property or a relation of a certain individual x in a domain of discourse. Using predicates, $P(x)$ can be viewed as a proposition about the individual x .

Note that a predicate itself is not a proposition, since saying ** is a philosopher* doesn't have any truth or false meaning to it, akin to a sentence fragment. But it is a placeholder $P(\cdot)$ upon which if an individual x is put in, it makes sense to ask whether $P(x)$ is true.

Definition 2.3 (Formula)

A **formula** is a string of propositions, connectives, predicates, and variables ϕ that turns into a proposition once all free variables have been instantiated.

With predicates alone, all we have really done is add notational convenience. However, if we want to state a proposition not just about x , but its domain of discourse, then we can use quantifiers.

Definition 2.4 (Quantifier)

A **quantifier** is an operator that specifies how many individuals in the domain of source satisfy a proposition. The two most used quantifiers are

1. *Universal Quantification*. \forall , which means *for every*.
2. *Existential Quantification*. \exists , which means *there exists*.

These quantifiers are additional symbols in our language \mathcal{L} . If we add the equality symbol, we get first-order logic with equality.

Axiom 2.1 (Equality)

Equality is a primitive logical symbol which is always interpreted as the real equality relation between members of the domain of discourse. These equality axioms are:

1. *Reflexivity*. For each variable x , $x = x$.
2. *Substitution for Functions*. For all variables x and y , and any function symbol f ,

$$x = y \implies f(x) = f(y) \quad (1)$$

3. *Substitution for Formulas.* For any variables x and y , and any formula $\phi(z)$ with free variable z , then

$$x = y \implies (\phi(x) \implies \phi(y)) \quad (2)$$

Symmetry and transitivity follow from the axioms above.

Ordinary first-order interpretations have a single domain of discourse over which all quantifiers range. **Many-sorted first-order logic**, or **typed first-order logic** allows variables to have different **sorts** or **types**, i.e. coming from different domains.

2.1 Exercises

Exercise 2.1 (Shifrin Abstract Algebra Appendix 1.1)

Negate the following sentences; in each case, indicate whether the original sentence or its negation is a true statement. Be sure to move the “not” through all the quantifiers.

1. For every integer $n \geq 2$, the number $2^n - 1$ is prime.
2. There exists a real number M so that for all real numbers t , $|\sin t| \leq M$.
3. For every real number $x > 0$, there exists a real number $y > 0$ so that $xy > 1$.

Solution 2.1

Listed.

1. *Negation.* For at least one $n \geq 2$, the number $2^n - 1$ is composite (not prime). The negation is true. Consider $n = 4 \implies 2^4 - 1 = 15 = 3 \cdot 5$.
2. *Negation.* There exists no real number M such that for all real numbers t , $|\sin t| \leq M$. The original is true. Pick $M = 1$, and by definition $|\sin t| \leq 1$.
3. *Negation.* For at least one real number $x > 0$, there exists no real number $y > 0$ so that $xy > 1$. The original is true. Given a real number $x > 0$, choose $y = \frac{1}{x} + 1$. Then,

$$xy = x \left(\frac{1}{x} + 1 \right) = 1 + x > 1 \quad (3)$$

where the steps follow from the ordered field properties of \mathbb{R} .

Exercise 2.2 (Shifrin Abstract Algebra Appendix 1.4)

Suppose n is an odd integer. Prove:

1. The equation $x^2 + x - n = 0$ has no solution $x \in \mathbb{Z}$.
2. Prove that for any $m \in \mathbb{Z}$, the equation $x^2 + 2mx + 2n = 0$ has no solution $x \in \mathbb{Z}$.

Solution 2.2

We prove by contradiction. Assume such a solution x exists for odd n . We consider the two cases where x

1. is even.

$$x \text{ is even} \implies x \equiv 0 \pmod{2} \quad (4)$$

$$\implies x^2 + x \equiv 0 \pmod{2} \quad (5)$$

$$\implies x^2 + x - n \equiv 1 \pmod{2} \quad (6)$$

2. is odd.

$$x \text{ is odd} \implies x \equiv 1 \pmod{2} \quad (7)$$

$$\implies x^2 + x \equiv 1 + 1 \equiv 0 \pmod{2} \quad (8)$$

$$\implies x^2 + x - n \equiv 1 \pmod{2} \quad (9)$$

Both cases result in the quadratic expression lying in the equivalence class [1] and thus cannot be 0. This contradicts our assumption that it is a solution. We prove by contradiction. Assume a solution x exists for odd n . Note that since $x^2 + 2mx + 2n \equiv x^2 \equiv 0 \pmod{2}$, this implies that $x \equiv 0 \pmod{2}$.^a Therefore, we can write $x = 2x'$ for some $x' \in \mathbb{Z}$, our assumption is equivalent to the existence of x' . Substituting this gives

$$4x'^2 + 4mx' + 2n = 0 \iff 2x'^2 + 2mx' + n = 0 \quad (10)$$

Since $2x'^2 + 2mx'$ is even, n must be even as well, which contradicts our assumption that n is odd.

3 Second-Order Logic

First order logic can quantify over individuals, but not over properties. That is, while we can state something like

There exists x such that x is a cube.

we cannot quantify over a predicate. That is, the statement

There exists a property P such that a cube satisfies P .

This statement does not make sense in first-order logic, but makes sense in second-order logic.

4 Naive Set Theory

Unlike axiomatic set theories, which are defined using formal logic, naive set theory was defined informally at the end of the 19th century by Cantor, in natural language (like English). It describes the aspects of mathematical sets using words (e.g. *satisfying, such as, ...*) and suffices for the everyday use of set theory in modern mathematics. However, as we will see, this leads to paradoxes.

Definition 4.1 (Set)

A **set** is a well-defined collection of distinct objects, called **elements**.

This definition tells us *what* a set is, but does not define *how* sets can be formed, and what operations on sets will again produce a set. The term *well-defined* cannot by itself guarantee the consistency and unambiguity of what exactly constitutes and what does not constitute a set, and therefore this is not a formal definition. Attempting to achieve this will be done in axiomatic set theory, like ZFC.

Definition 4.2 (Membership)

If x is a member of A , we write $x \in A$. For any x , it must be the case that either $x \in A$ (exclusive or) $x \notin A$.

^aThis is true if we look at the contrapositive: $x \equiv 1 \implies x^2 \equiv 1$.

Definition 4.3 (Equality)

Two sets A and B are defined to be equal, denoted as $A = B$, when they have precisely the same elements. That is, if $x \in A \iff x \in B$. This means that a set is completely determined by its elements, and the description is immaterial.

Definition 4.4 (Empty Set)

There exists an empty set, denoted \emptyset or $\{\}$, which is a set with no members at all. Because a set is described by its elements, there can only be one empty set.

Now we show how to construct sets.

Definition 4.5 (Set-Builder Notation)

We can construct a set in two ways.

1. We list its elements between curly braces.
 - (a) The set $\{1, 2\}$ denotes the set containing 1 and 2. By equality $\{1, 2\} = \{2, 1\}$.
 - (b) Repetition/multiplicity is irrelevant, and so $\{1, 2, 2\} = \{1, 1, 1, 2\} = \{1, 2\}$
2. We denote

$$S = \{x | P(x)\} \quad (11)$$

where P is a property. If x satisfies this property, then $x \in S$.

Naive set theory claims that this construction *always* produces a set. Therefore, a well-defined property is enough to always produce a set of elements satisfying P .

Example 4.1 (Empty Set)

Let $S = \{x | x \neq x\}$. For any x , $P(x)$ is false and so S contains no elements. Therefore $S = \emptyset$.

Example 4.2 (Singleton Set)

The set $\{x | x = a\} = \{a\}$.

Example 4.3 (Russell Set)

Let $R = \{x | x \notin x\}$, i.e. the set of all sets that do not contain themselves as elements.

Theorem 4.1 (Russell's Paradox)

The Russell set exists and does not exist.

Proof.

We will determine if R is an element of itself.

1. If $R \in R$, then by it does contain itself, so it does not satisfy the property and $R \notin R$.
2. If $R \notin R$, then it satisfies the property, so $R \in R$.

Therefore, it is both the case that $x \in R$ and $x \notin R$, which contradicts the membership definition. Therefore, R is both a set from set-builder construction and not a set due to the membership definition.

Theorem 4.2 (Existence of Universe)

Let U be the set of everything, known as the **universal set**. The universal set does exist and does not exist.

Proof.

We can define $U' = \{x \mid \{x\} = \{x\}\}$, which defines a set. Then the property P that $\{x\} = \{x\}$ is always true, and U' would contain everything, and by the definition of equality $U = U'$. Now since the Russell set R is both a set and not a set from Russell's paradox, we have $R \in U$ and $R \notin U$, which means that U cannot exist. Therefore U does not exist.

So the sufficiency a well-defined property to be able to construct a set is *too powerful* in that we can construct *any* set we want. This leads us to construct the Russell set, which opens up a lot of paradoxes. Therefore, we would like to restrict the notion of well-defined in a way, which leads to axiomatic set theories.

Definition 4.6 (Subsets)

Given two sets A and B , A is a **subset** of B if every element of A is also an element of B . A subset of B that is not equal to B is called a **proper subset**.

Theorem 4.3 (Equality)

It follows from the definition of equality that

$$A \subset B \text{ and } B \subset A \iff A = B \quad (12)$$

Definition 4.7 (Power Set)

The set of all subsets of a set A is called the **power set** of A , denoted by 2^A .

We could define other things like the union, etc., but I won't bother with it when I will define them for ZFC later.

5 Zermelo-Fraenkel-Choice (ZFC) Set Theory

So with these paradoxes in mind, we would like to construct an axiomatic formulation of sets. My take is to think that sets "exist" out there somewhere in the universe, and our job is to find them. Cantor with his naive set theory believed that for every meaningful property of things there is a set whose members are exactly all the things with that property. Russell shows this this cannot be the case. Nevertheless, *some* sets exist, and we have intuitive experience thinking about finite sets. Therefore, the axioms of set theory are a limited list of *assumptions* that we hope are true about that actually existing universe of sets. As long as they are true, then whatever we conclude from them by valid reasoning steps must also be true.¹ Hence we have the following definition, which first requires the familiar property of acting like a collection of something, and then obeys the axioms we set.

Definition 5.1 (Set)

A **set** X is anything

1. that has the innate property of containing elements, and
2. obeys the axioms of ZFC.

¹This idea is called naive Platonism.

Let's first talk about the language, where they are defined formally using the axioms in the next subsection. From first-order logic, note that we have the following symbols in our alphabet \mathcal{L}_{ZFC} .

1. The logical connectives \neg, \vee, \wedge .
2. The quantifier symbols \exists, \forall
3. Brackets $()$.

To represent sets, we also need symbols, and the membership property requires us to define a symbol for that too.

1. A countably infinite amount of variables used for representing sets.
2. The set membership symbol \in . In fact, when we say $x \in A$, this is a proposition formed from the predicate $P(x)$.

This is what we have to work with so far. We will construct the rest of the symbols ($=, \subset, \supset, \cup, \cap$) from the axioms. So far we don't even know if there exists any set that obeys the following axioms! Therefore, we will assert the existence of at least one set, namely the empty set.

5.1 ZF Axioms

Now we state the axioms, which is the foundation of ZF set theory.

Axiom 5.1 (Empty Set)

The empty set containing no elements exists.

Definition 5.2 (Empty Set)

The empty set is denoted \emptyset .

This asserts the existence of at least 1 set, which we will build on to create more sets.

Axiom 5.2 (Axiom of Extensionality)

Two sets are equal (are the same set) if they have the same elements.

$$\forall A \forall B [\forall x (x \in A \iff x \in B) \iff A = B] \quad (13)$$

Definition 5.3 (Equality)

This axiom allows us to define the equality operator $=$, which we now add to our alphabet.

Theorem 5.1 (Sets Don't Contain Repeated Elements)

Furthermore, this axiom also implies that sets are unique up to distinct elements. That is,

$$\{1, 1, 2\} = \{1, 2\} = \{1, 1, 2, 2\} \quad (14)$$

Axiom 5.3 (Axiom of Regularity)

Every non-empty set A contains a member x such that A and x are disjoint sets.

$$\forall A [A \neq \emptyset \implies \exists x (x \in A \wedge A \cap x = \emptyset)] \quad (15)$$

This, along with the axioms of pairing and union, implies that no set is an element of itself and that every set has an ordinal rank.

The axiom assists us in regulating which sets are viable and which are not, preventing Russell's paradox.

Axiom 5.4 (Axiom Schema of Restricted Comprehension, or Specification)

Subsets, like in naive set theory, are constructed using set builder notation. In general, the **subset** of a set A obeying a formula $\phi(x)$ with one free variable x may be written as

$$\{x \in A \mid \phi(x)\} \quad (16)$$

The axiom schema of specification states that this subset always exists.^a

Definition 5.4 (Subset, Superset)

The axiom of specification allows us to denote subsets. Notationally, if A is a subset of B , then we write $A \subset B$. Similarly, we say A is a **superset** of B , written $A \supset B$, if $B \subset A$.

Definition 5.5 (Intersection)

This also allows us to define intersection as

$$A \cap B := \{x \in A \mid x \in B\} \quad (17)$$

and we can define the intersection of an arbitrary collection of sets \mathcal{F} as the following. Let $A \in \mathcal{F}$.

$$\bigcap \mathcal{F} := \{x \in A \mid \forall B (B \in \mathcal{F} \implies x \in B)\} \quad (18)$$

Unfortunately, the union cannot be expressed in this specification schema, and we need a separate axiom for this.

Definition 5.6 (Set Minus)

We can however define set minus. Given sets A, B

$$A \setminus B := \{x \in A \mid x \notin B\} \quad (19)$$

Definition 5.7 (Set Complement)

Given B and a subset $A \subset B$, the **complement** of A with respect to B is

$$A^c := \{x \in B \mid x \notin A\} = B \setminus A \quad (20)$$

Axiom 5.5 (Axiom of Pairing)

If A, B are sets, then there exists a set which contains A and B as elements.^a

$$\forall A \forall B \exists C ((A \in C) \wedge (B \in C)) \quad (21)$$

This allows us to construct sets from old ones.

^aNote that this axiom does not allow the construction of entities of the more general form $\{x \mid \phi(x)\}$. This restriction is obviously needed to avoid Russell's paradox, hence the name *restricted* comprehension.

Theorem 5.2 (Nested Sets)

By the axiom of pairing, if we have a set X , then $\{X\}$ is also a set, since we can set $A = B = X$ which asserts the existence of $\{X, X\} = \{X\}$.

Axiom 5.6 (Axiom of Union)

For any set of sets \mathcal{F} , there is a set A containing every element that is a member of \mathcal{F} .

$$\forall \mathcal{F} \exists A \forall X \forall x [(x \in X \wedge X \in \mathcal{F}) \implies x \in A] \quad (22)$$

This formula doesn't directly assert the existence of $\cup \mathcal{F}$ (?).

Definition 5.8 (Union)

The set $\cup \mathcal{F}$ can be constructed from A in the above using the axiom schema of restricted comprehension.

$$\cup \mathcal{F} = \{x \in A \mid \exists X (x \in X \wedge X \in \mathcal{F})\} \quad (23)$$

Axiom 5.7 (Axiom of Infinity)

The axiom of infinity guarantees the existence of at least one infinite set. That is, given a set w , let $S(w) = w \cup \{w\}$ be a set.^a Then, there exists a set X such that

1. $\emptyset \in X$, and
2. if $w \in X$, then $S(w) \in X$.

In logic terms,

$$\exists X [\emptyset \in X \wedge \forall y (y \in X \implies S(y) \in X)] \quad (24)$$

Since we have axiomatically claimed the two premises to be true, by propositional logic, namely *modus ponens*, this implies the existence of at least one set X with infinitely many members.

Definition 5.9 (Von Neumann Ordinals)

The **Von Neumann ordinals** is the minimal set X satisfying the axiom of infinity. It is the set containing

$$\begin{aligned} 0 &= \{\} = \emptyset \\ 1 &= \{0\} = \{\emptyset\} \\ 2 &= \{0, 1\} = \{\emptyset, \{\emptyset\}\} \\ 3 &= \{0, 1, 2\} = \{\emptyset, \{\emptyset\}, \{\emptyset, \{\emptyset\}\}\} \\ 4 &= \{0, 1, 2, 3\} = \{\emptyset, \{\emptyset\}, \{\emptyset, \{\emptyset\}\}, \{\emptyset, \{\emptyset\}, \{\emptyset, \{\emptyset\}\}\}\} \\ &\dots = \dots \end{aligned}$$

This provides the foundation to construct the most basic mathematical sets: the natural numbers denoted \mathbb{N} .

^aFor example, if $A = \{1, 2\}$ and $B = \{2, 3\}$, then $\{\{1, 2\}, \{2, 3\}\}$ exists.

^aSince w is a set, by the axiom of pairing $\{w\}$ is a set, and by the axiom of union $w \cup \{w\}$ is a set.

Axiom 5.8 (Axiom of Power Set)

The axiom of power set states that for any set A , there is a set B that contains every subset^a of A .

$$\forall A \exists B \forall S (S \subset A \implies S \in B) \quad (25)$$

The axiom of schema of specification is then used to define the power set as the subset of such B containing the subset of A exactly.

$$2^X = \{Y \in B \mid Y \subset X\} \quad (26)$$

Definition 5.10 (Cartesian Product)

The power set axiom allows for the definition of the **Cartesian product** of two sets X and Y . Note that if $x \in X, y \in Y$, then by the axiom of union $x, y \in X \cup Y$ and by the axiom of power set $\{x\}, \{x, y\} \in \mathcal{P}(X \cup Y)$. Therefore, using the axiom of power set again we can define

$$(x, y) := \{\{x\}, \{x, y\}\} \in \mathcal{P}(\mathcal{P}(X \cup Y)) \quad (27)$$

and the Cartesian product is defined

$$X \times Y := \{(x, y) \in \mathcal{P}(\mathcal{P}(X \cup Y)) \mid x \in X \wedge y \in Y\} \quad (28)$$

which is axiomatically a valid set by the axiom schema of specification. From this we can define the Cartesian product of any finite collection of sets recursively.

5.2 Functions and Relations

The definition of Cartesian products allows us to formally define **correspondences**. The most notable correspondences are *functions* and *relations*.

Definition 5.11 (Function)

Given two sets X, Y , a function $f : X \rightarrow Y$ is a subset $f \subset X \times Y$ satisfying the following

1. For all $x \in X$, there exists $y \in Y$ s.t. $(x, y) \in f$.^a
2. For all $x \in X$ and $y, y' \in Y$, if $(x, y) \in f$ and $(x, y') \in f$, then $y = y'$.^b

The set X is said to be the **domain** and Y the **codomain**.

Definition 5.12 (Image, Preimage)

Given some $f : X \rightarrow Y$ and $A \subset X$, the **image** of A under f is defined

$$f(A) := \{y \in Y \mid \exists x \in X (f(x) = y)\} \quad (29)$$

Given $B \subset Y$, the **preimage** of B under f is defined

$$f^{-1}(B) := \{x \in X \mid f(x) \in B\} \quad (30)$$

Axiom 5.9 (Axiom Schema of Replacement)

This axiom asserts that the image of a set under any definable function will fall inside a set.

^aNote that subset is defined by the axiom of restricted comprehension.

^aThis says that f must be defined for all inputs in X .

^bIn other words, f must map one element to exactly one element.

Definition 5.13 (Injectivity, Surjectivity, Bijectivity)

A function $f : X \rightarrow Y$ is said to be

1. **injective** if $\forall x \in X, \forall x' \in X (f(x) = f(x') \implies x = x')$.
2. **surjective** if $\forall y \in Y \exists x \in X (y = f(x))$.
3. **bijective** if it is injective and surjective.

Definition 5.14 (Inverse Function)

If a function $f : X \rightarrow Y$ is bijective, then there exists an **inverse function** $f^{-1} : Y \rightarrow X$ satisfying

$$\forall x \in X [f(f^{-1}(x)) = f^{-1}(f(x)) = x] \quad (31)$$

Definition 5.15 (Relation)

A binary relation R on a set A is a subset of $A \times A$. We write aRb if and only if $(a, b) \in R$.^a A relation may have the following properties.

1. *Reflexive*. For all $a \in A$, aRa
2. *Symmetric*. For all $a, b \in A$, if aRb then bRa
3. *Antisymmetric*. For all $a, b \in A$, if aRb and bRa then $a = b$
4. *Transitive*. For all $a, b, c \in A$, if aRb and bRc then aRc
5. *Total*. For all $a, b \in A$, either aRb or bRa

Again, how do we even know for sure that these axioms aren't contradictory? The answer is that we don't, and that is why we take them as axioms rather than provable theorems. Fortunately, from the formulation in the early 20th century up until now, no contradictions have been found, and if there is one, then it would be very bad news for us.

5.3 Axiom of Choice

The axioms up to this point are pretty much undisputed and completes ZF set theory. The next one, though controversial, is required in the proofs of some notable theorems. If we include this axiom of choice, then we have ZFC set theory. The axiom of choice has many equivalent definitions. Informally, note that we have defined the Cartesian product for a finite family of sets. Consequently, functions and relations are also defined for a finite collection of elements from each set. Now we try to extend this to an arbitrary (countably or uncountably infinite, though we haven't defined these terms yet) collection of sets.

Colloquially, the axiom of choice says that a Cartesian product of a collection² of non-empty sets is non-empty. That is, it is possible to construct a new set by choosing one element from each set, even if the collection is infinite.

Axiom 5.10 (Axiom of Choice)

For every indexed family $X = \{S_i\}_{i \in I}$ of nonempty sets, there exists an indexed set $\{x_i\}_{i \in I}$ such that $x_i \in S_i$ for every $i \in I$.

Definition 5.16 (Choice Function)

This mapping $f : X \rightarrow \cup_{i \in I} S_i$ that maps $S_i \mapsto x_i \in S_i$ is called a **choice function**. Despite the name, it is not a function according to our definition if I is not finite, and so we must axiomatically construct this.

^aIt is a way of describing precisely which two elements are related to one another.

²Note that this does not have to be finite

The existence of a choice function when X is finite is easily proved from the ZF axioms, and AC only matters for certain infinite sets. It is understandable how this is controversial, since we don't really work with functions over infinite Cartesian products. It is characterized as nonconstructive because it asserts the existence of a choice function but says nothing about how to construct one, unlike the axiom of infinity.

This choice function was used in the proof of the following, which turns out to be equivalent.

Axiom 5.11 (Axiom of Well-Ordering)

For any set X , there exists a binary relation R which *well-orders* X , i.e. is a total order and has the property that every nonempty subset of X has a least element under the order R .

$$\forall X \exists R (R \text{ well-orders } X) \quad (32)$$

We can see generally that we would like to use a choice function to select a representative element of each set in X . Then we can use these to construct an order. Finally, we state the last form of the axiom of choice.

Axiom 5.12 (Zorn's Lemma)

Let X be a partially ordered set that satisfies the two properties.

1. P is nonempty.
2. Every *chain* (a subset $A \subset P$ where A is totally ordered) has an upper bound in P .

Then P has at least one maximal element.

Zorn's lemma is required to show that every vector space has a basis. With the axiom of choice, we can define the cardinality.

Definition 5.17 (Cardinality)

5.4 Rules of Set Theory

Let's first talk about rules following the union, intersection, and set minus operators.

Theorem 5.3 (deMorgan's Laws)

The following hold for sets X, Y, Z .

$$X \cap (Y \cup Z) = (X \cap Y) \cup (X \cap Z) \quad (33)$$

$$X \cup (Y \cap Z) = (X \cup Y) \cap (X \cup Z) \quad (34)$$

$$X \setminus (Y \cup Z) = (X \setminus Y) \cap (X \setminus Z) \quad (35)$$

$$X \setminus (Y \cap Z) = (X \setminus Y) \cup (X \setminus Z) \quad (36)$$

Proof.

Theorem 5.4 (Symmetric Difference)

Given sets X, Y ,

$$(X \setminus Y) \cap (Y \setminus X) = (X \cup Y) - (X \cap Y) \quad (37)$$

Proof.

Now let's see how these operations behavior under functions.

Theorem 5.5 (Preservation Under Mapping Back and Forth)

Given $f : A \rightarrow B$, with $A_0, A_1 \subset A$ and $B_0, B_1 \subset B$, the following hold

1. $A_0 \subset f^{-1}(f(A_0))$, with equality holding if f is injective.
2. $f(f^{-1}(B_0)) \subset B_0$, with equality holding if f is surjective.

Proof.

Listed.

1. Assume that $x \in A_0$. Then $f(x) \in f(A_0)$. The preimage is

$$f^{-1}(f(A_0)) := \{y \in A \mid f(y) \in f(A_0)\} \quad (38)$$

and x certainly satisfies the condition that $f(x) \in f(A_0)$. Therefore $x \in f^{-1}(f(A_0))$ and so $A_0 \subset f^{-1}(f(A_0))$.

Now assume that f is injective. It suffices to prove that $f^{-1}(f(A_0)) \subset A_0$ since the other direction is proven for all functions. We prove this by proving the contrapositive, i.e. $x \notin A_0 \implies x \notin f^{-1}(f(A_0))$. Suppose $x \notin A_0 \implies f(x) \notin f(A_0) \implies f^{-1}(f(x)) \not\subset f^{-1}(f(A_0))$ by definition of the image and preimage. But note that since f is injective, $f^{-1}(f(x)) = x$.^a and thus $x \notin f^{-1}(f(A_0))$.

2. We prove this using the contrapositive. Assume that $x \notin B_0$. Then, with abuse of notation, we have by definition of the preimage and the image $f^{-1}(x) \not\subset f^{-1}(B_0) \implies f(f^{-1}(x)) \not\subset f(f^{-1}(B_0))$. But $f(f^{-1}(x)) = \{x\}$, since we are just mapping the preimage of x back across to f . Therefore, $x \notin f(f^{-1}(B_0))$.

Now assume that f is surjective. It suffices to prove that $B_0 \subset f(f^{-1}(B_0))$. Assume $y \in B_0$. Since f is surjective, we know that $f^{-1}(y)$ is nonempty in A . We can state $f^{-1}(y) \subset f^{-1}(B_0)$ ^b which then implies $f(f^{-1}(y)) \subset f(f^{-1}(B_0))$.^c But $f(f^{-1}(y)) = y$ as mentioned previously, and so $y \in f(f^{-1}(B_0))$.

Example 5.1 ()

To see why equality does not hold in general for the two cases, look at the counterexamples below.

1. $A_0 \not\subset f^{-1}(f(A_0))$.
2. $f(f^{-1}(B_0)) \not\subset B_0$. Consider $X = Y = \{0, 1\}$ and $f : X \rightarrow Y$ defined $f(0) = f(1) = 0$. Consider $C = Y$. We have $f^{-1}(C) = f^{-1}(0) \cup f^{-1}(1) = X \cup \emptyset = X$. Then $f(f^{-1}(C)) = f(X) = \{0\} \neq C$.

Theorem 5.6 (Preservation Under Preimages)

Given $f : A \rightarrow B$, with $A_0, A_1 \subset A$ and $B_0, B_1 \subset B$, f preserves the inclusion, union, intersection, and set difference under the preimage.

1. *Inclusion.* $B_0 \subset B_1 \implies f^{-1}(B_0) \subset f^{-1}(B_1)$.
2. *Union.* $f^{-1}(B_0 \cup B_1) = f^{-1}(B_0) \cup f^{-1}(B_1)$.
3. *Intersection.* $f^{-1}(B_0 \cap B_1) = f^{-1}(B_0) \cap f^{-1}(B_1)$.

^aMore specifically, if we treat x as the singleton set, $f(x)$ is also a singleton set by definition of a function. Since f is injective, the preimage of a singleton set must be a singleton set. If it were not, then there exists x, y with $x \neq y$ that maps to the same z , which contradicts the definition of injectivity.

^bThe formal proof of this is given in Munkres 1.2.2.a.

^cAgain formal proof of this given in Munkres 1.2.2.e.

4. *Set Difference.* $f^{-1}(B_0 \setminus B_1) = f^{-1}(B_0) \setminus f^{-1}(B_1)$.

Proof.

Listed.

1. *Inclusion.* If $x \in B_0$, then $f^{-1}(x) \subset A$ maps to x by definition. But since $x \in B_0$, $f^{-1}(x)$ maps to a point in B_0 , and so $f^{-1}(x) \subset f^{-1}(B_0)$. Since $B_0 \subset B_1$ by assumption, $x \in B_1$, and by the previous logic but with B_0 replaced by B_1 we have $f^{-1}(x) \subset f^{-1}(B_1)$. We have just proved that $f^{-1}(x) \in f^{-1}(B_0) \implies f^{-1}(x) \in f^{-1}(B_1)$, and so $f^{-1}(B_0) \subset f^{-1}(B_1)$.

2. *Union.* We prove bidirectionally.

- (a) $f^{-1}(B_0 \cup B_1) \subset f^{-1}(B_0) \cup f^{-1}(B_1)$. Let $x \in f^{-1}(B_0 \cup B_1)$ which by definition of the preimage means $f(x) \in B_0 \cup B_1$. Therefore $f(x) \in B_0$ or B_1 . Without loss of generality, let $f(x) \in B_0$. Then we have

$$x \in f^{-1}(f(x)) \subset f^{-1}(B_0) \quad (39)$$

where the first inclusion comes from [Munkres 1.2.1.a] when treating $A_0 = \{x\}$, and the second subset comes from [Munkres 1.2.2.a] when treating $B_0 = \{f(x)\}$, $B_1 = B_1$. Therefore $x \in f^{-1}(B_0) \subset f^{-1}(B_0) \cup f^{-1}(B_1)$.

- (b) $f^{-1}(B_0) \cup f^{-1}(B_1) \subset f^{-1}(B_0 \cup B_1)$. Let $x \in f^{-1}(B_0) \cup f^{-1}(B_1)$. Without loss of generality, let $x \in f^{-1}(B_0)$ which by definition of the preimage implies $f(x) \in B_0 \subset (B_0 \cup B_1) \implies f(x) \in (B_0 \cup B_1)$. Therefore, we have

$$x \in f^{-1}(f(x)) \subset f^{-1}(B_0 \cup B_1) \quad (40)$$

where the inclusion claim comes from [Munkres 1.2.1.a] when treating $A_0 = \{x\}$, and the subset claim comes from [Munkres 1.2.2.a] when treating $B_0 = \{f(x)\}$, $B_1 = B_0 \cup B_1$. Therefore $x \in f^{-1}(B_0 \cup B_1)$.

Therefore, $f^{-1}(B_0) \cup f^{-1}(B_1) = f^{-1}(B_0 \cup B_1)$.

3. *Intersection.* We prove bidirectionally.

- (a) $f^{-1}(B_0 \cap B_1) \subset f^{-1}(B_0) \cap f^{-1}(B_1)$. Assume $x \in f^{-1}(B_0 \cap B_1)$, which by definition of the preimage means $f(x) \in B_0 \cap B_1$. So

$$f(x) \in B_0 \implies x \in f^{-1}(f(x)) \subset f^{-1}(B_0) \quad (41)$$

$$f(x) \in B_1 \implies x \in f^{-1}(f(x)) \subset f^{-1}(B_1) \quad (42)$$

where the inclusion claim comes from [Munkres 1.2.1.a] when treating $A_0 = \{x\}$, and the subset claim comes from [Munkres 1.2.2.a] when treating $f(x)$ as a singleton set. Therefore x is in both of the preimages and so $x \in f^{-1}(B_0) \cap f^{-1}(B_1)$.

- (b) $f^{-1}(B_0) \cap f^{-1}(B_1) \subset f^{-1}(B_0 \cap B_1)$. Let $x \in f^{-1}(B_0) \cap f^{-1}(B_1)$. Then by definition of intersection and preimage,

$$x \in f^{-1}(B_0) \implies f(x) \in B_0 \quad (43)$$

$$x \in f^{-1}(B_1) \implies f(x) \in B_1 \quad (44)$$

and so $f(x) \in B_0 \cap B_1$ by definition of intersection. This means by definition of the preimage that $x \in f^{-1}(B_0 \cap B_1)$.

4. *Set Difference.* We prove bidirectionally.

- (a) $f^{-1}(B_0 \setminus B_1) \subset f^{-1}(B_0) \setminus f^{-1}(B_1)$. Let $x \in f^{-1}(B_0 \setminus B_1)$ which by definition of preimage means $f(x) \in B_0 \setminus B_1$. This implies two things. First,

$$f(x) \in B_0 \implies x \in f^{-1}(f(x)) \subset f^{-1}(B_0) \quad (45)$$

where the inclusion comes from [Munkres 1.2.1.a] when treating $A_0 = \{x\}$ as the single set, and the subset claim comes from [Munkres 1.2.2.a] stating that inclusions are preserved

under the preimage operator. Secondly, we claim that

$$f(x) \notin B_1 \implies x \notin f^{-1}(B_1) \quad (46)$$

since if $x \in f^{-1}(B_1)$, then $f(x) \in B_1$ by definition of the preimage.

(b) $f^{-1}(B_0) \setminus f^{-1}(B_1) \subset f^{-1}(B_0 \setminus B_1)$. Let $x \in f^{-1}(B_0) \setminus f^{-1}(B_1)$. Then the following holds

$$x \in f^{-1}(B_0) \implies f(x) \in B_0 \quad (47)$$

$$x \notin f^{-1}(B_1) \implies f(x) \notin B_1 \quad (48)$$

from the definition of the preimage and the contrapositive of its implication. Therefore $f(x) \in B_0 \setminus B_1$ which by definition of the preimage $x \in f^{-1}(B_0 \setminus B_1)$.

Theorem 5.7 (Preservation Under Images)

Given $f : A \rightarrow B$, with $A_0, A_1 \subset A$ and $B_0, B_1 \subset B$, f preserves the inclusion and union under the image, but inclusion properties for the intersection and set difference hold.

1. *Inclusion.* $A_0 \subset A_1 \implies f(A_0) \subset f(A_1)$.
2. *Union.* $f(A_0 \cup A_1) = f(A_0) \cup f(A_1)$.
3. *Intersection.* $f(A_0 \cap A_1) \subset f(A_0) \cap f(A_1)$, and equality holds if f is injective.
4. *Set Difference.* $f(A_0 \setminus A_1) \supset f(A_0) \setminus f(A_1)$, and equality holds if f is injective.

Proof.

Listed.

1. *Inclusion.* Let $x \in A_0$. Then by definition of the image $f(x) \in f(A_0)$. Since $A_0 \subset A_1$, then $x \in A_1$ and it immediately follows that $f(x) \in f(A_1)$. Therefore $f(A_0) \subset f(A_1)$.
2. *Union.* We prove bidirectionally.
 - (a) $f(A_0 \cup A_1) \subset f(A_0) \cup f(A_1)$. Let $y \in f(A_0 \cup A_1)$. Then by definition there exists some $x \in A_0 \cup A_1$ s.t. $f(x) = y$. WLOG let $x \in A_0$. Then by definition $y = f(x) \in f(A_0) \subset f(A_0) \cup f(A_1)$.
 - (b) $f(A_0) \cup f(A_1) \subset f(A_0 \cup A_1)$. Let $y \in f(A_0) \cup f(A_1)$. WLOG $y \in f(A_0)$, and there exists some $x \in A_0$ s.t. $f(x) = y$. Since $x \in A_0$, $x \in A_0 \cup A_1$, and by definition $y = f(x) \in f(A_0 \cup A_1)$.
3. *Intersection.* Assume that $y \in f(A_0 \cap A_1)$. Then by definition there exists some $x \in A_0 \cap A_1$ s.t. $f(x) = y$. So we have

$$x \in A_0 \implies f(x) \in f(A_0) \quad (49)$$

$$x \in A_1 \implies f(x) \in f(A_1) \quad (50)$$

and therefore $y = f(x) \in f(A_0) \cap f(A_1)$.

To prove equality, it suffices to show that $f(A_0) \cap f(A_1) \subset f(A_0 \cap A_1)$ if f is injective. Assume that $y \in f(A_0) \cap f(A_1)$. Then $y \in f(A_0)$, and so there exists an $x \in A_0$ s.t. $y = f(x) \in f(A_0)$. By the same logic there exists an $x' \in A_1$ s.t. $y = f(x') \in f(A_1)$. But since f is injective, this implies that $x = x'$. So $x \in A_0 \cap A_1$, and so $y = f(x) \in f(A_0 \cap A_1)$.

4. *Set Difference.* Assume that $y \in f(A_0) \setminus f(A_1)$. Since $y \in f(A_0)$, there exists some $x \in A_0$ s.t. $y = f(x)$. Since $y \notin f(A_1)$, there exists no $x' \in A_1$ s.t. $y = f(x')$. Therefore, $x \in A_0 \setminus A_1 \implies y = f(x) \in f(A_0 \setminus A_1)$.

To prove equality, it suffices to show that $f(A_0 \setminus A_1) \subset f(A_0) \setminus f(A_1)$ if f is injective. Assume that $y \in f(A_0 \setminus A_1)$. Then there exists some $x \in A_0 \setminus A_1$ s.t. $f(x) = y$. We claim that x is unique since if there were two x, x' , then $f(x) = f(x')$ with $x \neq x'$, which means f is not injective. We see that $x \in A_0 \implies y = f(x) \in f(A_0)$, and $x \notin A_1 \implies y = f(x) \notin f(A_1)$. Therefore, $x \in f(A_0) \setminus f(A_1)$.

Example 5.2 (Intersection Not Necessarily Preserved)

Note that intersection is not necessarily preserved. To see why, look at the counterexample. Consider $A = \{0, 1\}, B = \{1, 2\}$, and define

$$f(0) = f(2) = 0, f(1) = 1 \quad (51)$$

Then $f(A) = f(B) = \{0, 1\} \implies f(A) \cap f(B) = \{0, 1\}$. On the other hand, we have $A \cap B = \{1\} \implies f(A \cap B) = \{1\}$.

Theorem 5.8 (Composition)

Let $f : X \rightarrow Y$ and $g : Y \rightarrow Z$.

1. f injective and g injective $\implies g \circ f$ injective.
2. f surjective and g surjective $\implies g \circ f$ surjective.
3. f bijective and g bijective $\implies g \circ f$ bijective.

Theorem 5.9 (Injectivity/Surjectivity)

Let $f : X \rightarrow Y, g : Y \rightarrow Z$, and $h = g \circ f$. The following hold:

1. h injective $\implies f$ injective.
2. h surjective $\implies g$ surjective.
3. h bijective $\implies f$ injective and g bijective.

Corollary 5.1 (Bijection Equals Existence of Inverse)

$f : X \rightarrow Y$ has an inverse function $f^{-1} : Y \rightarrow X$ iff it is bijective.

Corollary 5.2 (Decomposition)

Any function $h : X \rightarrow Y$ can be decomposed to the form $h = g \circ f$, where f is injective and g is surjective.

Theorem 5.10 (Inverse of Inverses)

If f is bijective, then $f = (f^{-1})^{-1}$.

Theorem 5.11 (Finite Set Mappings)

Suppose X and Y are finite sets, each with n elements, and $f : X \rightarrow Y$. If f is injective or surjective, then f is bijective.

Theorem 5.12 (Inverse of Compositions)

If f, g are both bijective, then

$$(f \circ g)^{-1} = g^{-1} \circ f^{-1} \quad (52)$$

5.5 Exercises

Exercise 5.1 (Shifrin Abstract Algebra Appendix 2.3)

Let $f : X \rightarrow Y$. Let $A, B \subset X$ and $C, D \subset Y$. Prove or give a counterexample (if possible, provide sufficient hypotheses for each statement to be valid):

1. $f(A) \cup f(B) = f(A \cup B)$
2. $f(A) \cap f(B) = f(A \cap B)$
3. $f(A - B) = f(A) - f(B)$
4. $f^{-1}(C) \cup f^{-1}(D) = f^{-1}(C \cup D)$
5. $f^{-1}(C) \cap f^{-1}(D) = f^{-1}(C \cap D)$
6. $f^{-1}(C - D) = f^{-1}(C) - f^{-1}(D)$
7. $f(f^{-1}(C)) = C$
8. $f^{-1}(f(A)) = A$

Solution 5.1

Listed.

- 1.

Exercise 5.2 (Munkres Topology 1.5.5)

Which of the following subset of \mathbb{R}^ω can be expressed as the Cartesian product of subsets of \mathbb{R} ?^a

Solution 5.2

Listed. We will denote the sets in question as A .

1. We claim that

$$A = \mathbb{Z} \times \mathbb{Z} \times \dots \quad (53)$$

2. Let us denote $\mathbb{R}_{\geq i}$ be the set of reals greater than or equal to i . This is clearly a subset of \mathbb{R} . Then

$$A = \prod_{i=1}^{\infty} \mathbb{R}_{\geq i} \quad (54)$$

3. We claim

$$A = \left(\prod_{i=1}^{100} \mathbb{R} \right) \times \left(\prod_{j=1}^{\infty} \mathbb{Z} \right) \quad (55)$$

4. This is not possible

6 Natural Numbers and Induction

Note that the axiom of infinity allows us to construct the ordinal numbers. This was based off of two things. First the assertion that the empty set is contained and that if a set w in the ordinal numbers, then $w \cup \{w\}$ is also contained. The second property has a name.

Definition 6.1 (Inductive Set)

Let X be a set. Then X is said to be **inductive** if every element has a **successor**, i.e. a construction of a different element y from x .

$$x \in X \implies f(x) \in X \quad (56)$$

^aNote that the existence of these sets depend on the axiom of choice.

A set $X \subset \mathbb{R}$ is inductive if for each number $x \in X$, it also contains $x + 1$.

From this, with a few more structures we can define the naturals.

Definition 6.2 (Natural Numbers)

The natural numbers \mathbb{N} is the set of von Neumann ordinals, with each element represented by a numerical symbol (e.g. $1, 2, \dots$).

$$\begin{aligned} 0 &= \{\} = \emptyset \\ 1 &= \{0\} = \{\emptyset\} \\ 2 &= \{0, 1\} = \{\emptyset, \{\emptyset\}\} \\ 3 &= \{0, 1, 2\} = \{\emptyset, \{\emptyset\}, \{\emptyset, \{\emptyset\}\}\} \\ 4 &= \{0, 1, 2, 3\} = \{\emptyset, \{\emptyset\}, \{\emptyset, \{\emptyset\}\}, \{\emptyset, \{\emptyset\}, \{\emptyset, \{\emptyset\}\}\}\} \\ &\dots = \dots \end{aligned}$$

The successor function $S(x)$ is rewritten in different notation as $S(x) = x + 1$. It also has the relation \leq defined as the set

$$\{(a, b) \in \mathbb{N} \times \mathbb{N} \mid \exists n (S^n(a) = b)\} \quad (57)$$

where S^n is the successor operation composed n times. Addition is defined as

$$a + b := S^b(a) = S^a(b) \quad (58)$$

and multiplication is defined recursively as

1. $m \times 0 := 0$.
2. $m \times (n + 1) := m \times n + m$

which is familiar to the process of adding m to itself n times.

Lemma 6.1 (Well Ordering Principle of Naturals)

Every nonempty subset of \mathbb{N} has a minimal element.

Proof.

Take a subset $A \subset \mathbb{N}$.

1. If $0 \in A$, the minimum is 0.
2. Else if $1 \in A$, the minimum is 1.
3. ...

We can use this inductive property of natural numbers to prove properties of them. Note that this can only be used to prove for finite (yet unbounded) numbers!

Lemma 6.2 (Induction Principle)

Given $P(n)$, a property depending on a natural number $n \in \mathbb{N}$,

1. if $P(n_0)$ is true for some $n_0 \in \mathbb{N}$, and
 2. if for every $k \geq n_0$, $P(k)$ true implies $P(k + 1)$ true,
- then $P(n)$ is true for all $n \geq n_0$.

Lemma 6.3 (Strong Induction Principle)

Given $P(n)$, a property depending on a positive integer n ,

1. if $P(n_0), P(n_0+1), \dots, P(n_0+m)$ are true for some positive integer n_0 , and nonnegative integer m , and
 2. if for every $k > n_0 + m$, $P(j)$ is true for all $n_0 \leq j \leq k$ implies $P(k)$ is true,
- then $P(n)$ is true for all $n \geq n_0$.

Theorem 6.1 (Equivalence of 3 Principles)

The well-ordering principle, induction principle, and the strong induction principle are all equivalent.

Proof.

We prove the steps.

1. *Well Ordering* \implies *Strong Induction*.
2. *Strong Induction* \implies *Induction*.
3. *Induction* \implies *Well-Ordering*.

The idea behind the strong induction principle leads to the proof using infinite descent. Infinite descent combines strong induction with the fact that every subset of the positive integers has a smallest element, i.e. there is no strictly decreasing infinite sequence of positive integers.

Theorem 6.2 (Infinite Descent)

Given $P(n)$, a property depending on positive integer, assume that $P(n)$ is false for a set of integers \mathcal{S} . Let the smallest element of \mathcal{S} be n_0 . If $P(n_0)$ false implies $P(k)$ false, where $k < n_0$, then by contradiction $P(n)$ is true for all n .

6.1 Exercises**Exercise 6.1 (Shifrin Abstract Algebra 1.1.4.C)**

We check for $n = 1$ denoting our formula as f . Indeed, we have

$$f(1) = \frac{1 \cdot 2 \cdot 3}{6} = 1 = 1^2 \quad (59)$$

For the induction step, assume that $f(k)$ is true for some $k \in \mathbb{N}$. Then,

$$f(k+1) = f(k) + (k+1)^2 \quad (60)$$

$$= \frac{k(k+1)(2k+1)}{6} + \frac{6(k+1)^2}{6} \quad (61)$$

$$= \frac{(k+1)\{k(2k+1) + 6(k+1)\}}{6} \quad (62)$$

$$= \frac{(k+1)(2k^2 + 7k + 6)}{6} \quad (63)$$

$$= \frac{(k+1)(k+2)(2(k+1)+1)}{6} \quad (64)$$

$$= f(k+1) \quad (65)$$

Therefore f holds for all $n \in \mathbb{N}$.

Exercise 6.2 (Shifrin Abstract Algebra 1.1.4.G)

We prove the base cases for $n = 1, 2, 3$.

1. $n = 1$. $n + 2 = 3$ is divisible by 3.
2. $n = 2$. $n + 4 = 6$ is divisible by 3.
3. $n = 3$. $n + 2 = 3$ is divisible by 3.

For our inductive step, assume that for some $n = k \in \mathbb{N}$, one of the elements in $S_k = \{k, k+2, k+4\}$ is divisible by 3. Let us denote this element a . We wish to show that this claim is true for $n = k+3$ on the set $S_{k+3} = \{k+3, k+5, k+7\}$. Since $a \in S_k$, this means that $a+3 \in S_{k+3}$, and $3|a \implies 3|(a+3)$. So we can always identify the element $a+3$. Since we proved the base cases for $n = 1, 2, 3$, and proved the recursive step, we have essentially proved the claim for all naturals of the form $3k+1, 3k+3, 3k+3$ ($k \in \mathbb{N}_0$), which is precisely the natural numbers.

Exercise 6.3 (Shifrin Abstract Algebra 1.1.4.J)

Let $n = 1$. Then $1 + x \geq 1 + x$ trivially. For the induction step, assume that this inequality holds for some $n \in \mathbb{N}$. Then, we have

$$1 + (n+1)x = 1 + nx + x \quad (66)$$

$$\leq (1+x)^n + x \quad (67)$$

$$\leq (1+x)^n + x(1+x)^n \quad (68)$$

$$= (1+x)^{n+1} \quad (69)$$

where we prove the penultimate step by applying the ordered field axioms to the 2 cases:

1. If $x \geq 0$, then addition preserves order so $1+x \geq 0+1 = 1$. Since $1+x, 1 > 0$, order is preserved under multiplication by a positive element, so $(1+x)^2 \geq 1+x \geq 1$. Using induction, we can show that for all $n \in \mathbb{N}$, $(1+x)^n \geq 1$, and again by preservation of order under multiplication by a positive element, this implies $x(1+x)^n \geq x$ for all $n \in \mathbb{N}$.
2. If $0 > x > -1$, we have $0 < 1+x < 1$ and by the same induction proof, we can bound $0 < (1+x)^n < 1$ for all n . Finally by reversal of order under multiplication by a negative element, we have $x(1+x)^n > x$.

Therefore, we take the less restrictive of the 2 bounds: $x(1+x)^n \geq x$.

Exercise 6.4 (Shifrin Abstract Algebra 1.1.7)

Let us denote

$$x = \frac{1+\sqrt{5}}{2}, \quad y = \frac{1-\sqrt{5}}{2} \quad (70)$$

Note the identities

$$x^2 = \left(\frac{1+\sqrt{5}}{2}\right)^2 = \frac{3+2\sqrt{5}}{2} = 1+x \quad (71)$$

$$y^2 = \left(\frac{1-\sqrt{5}}{2}\right)^2 = \frac{3-2\sqrt{5}}{2} = 1+y \quad (72)$$

We check the base case for $n = 1$

$$a_1 = \frac{1}{\sqrt{5}}(x+y) = \frac{1}{\sqrt{5}} \frac{2\sqrt{5}}{2} = 1 \quad (73)$$

and for $n = 2$

$$a_2 = \frac{1}{\sqrt{5}}(x^2 - y^2) = \frac{1}{\sqrt{5}}((1+x) - (1+y)) = \frac{1}{\sqrt{5}}(x-y) = a_1 = 1 \quad (74)$$

For the inductive step, assume that this formula holds for some $k - 1, k \in \mathbb{N}$. Then, we have

$$a_{k+1} = a_k + a_{k-1} \quad (75)$$

$$= \frac{1}{\sqrt{5}}(x^{k-1} - y^{k-1}) + \frac{1}{\sqrt{5}}(x^k - y^k) \quad (76)$$

$$= \frac{1}{\sqrt{5}}\{x^{k-1}(1+x) - y^{k-1}(1+y)\} \quad (77)$$

$$= \frac{1}{\sqrt{5}}(x^{k+1} - y^{k+1}) \quad (78)$$

and we are done.

7 Cardinality

Definition 7.1 (Equipotence)

Two sets A and B are **equipotent**, written $A \approx B$, if there exists a bijective map $f : A \rightarrow B$. This implies that their cardinalities are the same: $|A| = |B|$. It has the following properties:

1. Reflexive: $A \approx A$
2. Symmetric: $A \approx B$ implies $B \approx A$
3. Transitive: $A \approx B$ and $B \approx C$ implies $A \approx C$

Definition 7.2 ()

For any positive integer n , let J_n be the set whose elements are the integers $1, 2, \dots, n$. For any set A , we define

1. A is **finite** if $A \approx J_n$ for some n . The empty set is also considered to be finite.
2. A is **infinite** if it is not finite.
3. A is **countable** if $A \approx \mathbb{N}$.
4. A is **uncountable** if A is neither finite nor countable.
5. A is **at most countable** if A is finite or countable.

At this point, we may already be familiar with the fact that \mathbb{Q} is countable and \mathbb{R} is uncountable. Let us formalize the statement that a countable infinity is the smallest type of infinity. We can show this by taking a countable set and showing that every infinite subset must be countable. If it was uncountable, then this would mean that a countable set contains an uncountable set.

Theorem 7.1 ()

Every infinite subset of a countable set A is countable.

Theorem 7.2 ()

An at most countable union of countable sets is countable.

Theorem 7.3 ()

A finite Cartesian product of countable sets is countable.

Corollary 7.1 ()

\mathbb{Q} is countable.

Now, how do we prove that a set is uncountable? We can't really use the contrapositive of Theorem 7, since to prove that an arbitrary set A is uncountable, then we must find an infinite subset that is not countable. But now we must prove that this subset itself is not countable, too! Therefore, we can use this theorem.

Theorem 7.4 ()

Given an arbitrary set A , if every countable subset B is a proper subset of A , then A is uncountable.

Proof.

Assume that A is countable. Then A itself is a countable subset of A , but by the assumption, A should be a proper subset of A , which is absurd. Therefore, A is uncountable.

Theorem 7.5 ()

Let A be the set of all sequences whose elements are the digits 0 and 1. Then, A is uncountable.
